

AURA — Database schema (ERD)

Entity-relationship diagram for the v1 schema. All eight tables, every foreign key, and crow's-foot cardinality.

This maps 1:1 to `lib/db/schema.ts` — each entity is a Drizzle `pgTable`, each `(FK)` is a `.references()`, and each `(UK)` is a unique or partial-unique index. The per-tenant uniqueness markers (`patients.phone`, `patients.external_patient_id`, `conversations.patient_id`) are **partial** indexes — unique only where the value is non-null.

Reading notes

- `tenants` is the hub. Six tables carry a `tenant_id` FK back to it — that column is what every Row-Level Security policy filters on.
- `tenant_id` is denormalized onto `messages` even though `messages` already reaches a tenant via `conversation_id`. This is deliberate: RLS policies must filter on a `tenant_id` column present **on the table itself**, not via a join.
- `patients` to `conversations` is a strict one-to-one, enforced by the unique index on `conversations(tenant_id, patient_id)` — not just convention.
- `messages.sent_by_user_id` is nullable: inbound messages and automated sends have no operator.
- `admin_users` has no `tenant_id` — internal staff are not tenant-scoped.
`admin_audit_log.tenant_id_accessed` is nullable because tenant-list views touch no specific tenant.

Rendering

This file renders as a diagram automatically on:

- **GitHub** — native mermaid support in any `.md` file, no setup.
- **VS Code** — install the *Markdown Preview Mermaid Support* extension, then open the markdown preview (`Cmd/Ctrl + Shift + V`).
- **Most static-site generators** (MkDocs Material, Docusaurus, etc.) — mermaid is built in or a one-line plugin.

If a viewer doesn't support mermaid, the diagram falls back to a readable fenced code block.
